Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

EP 0 426 434 B1

Description

Background of the invention

1. Field of the Invention

This invention relates in general to sugar beet pectins. In one aspect, this invention is directed to a pectin extract obtained from sugar beet. In another aspect, this invention relates to sugar beet pectin having utility in comestibles.

2. Background of the Related Art

Spent sugar beet pulp consists largely of structural polysaccharide complexes associated with the primary cell wall of parenchymatous tissue. This tissue has been subjected to an exhaustive hot water extraction to remove sugar and other intracellular constituents. Subsequent extraction of spent beet pulp under hydrolytic conditions generates solubilised forms of the non-cellulosic components whose yield and chemical classification vary depending on the severity of hydrolysis condition and the specific extractive method employed. Past reports tended to segregate the solubilised polysaccharides into largely neutral carbohydrate complexes (hemicelluloses) and acidic carbohydrate complexes (pectins). More recent investigations suggest that both the neutral and acidic carbohydrates may be covalently associated components of the non-cellulosic structural macropolysaccharides comprising the cell wall of parenchymatous plant tissue.

Commercial pectins are derived from citrus and apple pulps. They are characterized by high viscosity of low solids aqueous solutions and form gels in the presence of high solids sucrose solutions under mildly acidic conditions. Commercial pectins derived from other plant sources have long been sought. Commercial pectin production from sugar beet commenced in Europe during World War II but ceased when citrus and apple pulps again became available. Sugar beet pectins were generally of inferior jelly grade and their function was enhanced by conversion to low ester pectinic acids which produce ionically crosslinked gels in the presence of polyvalent cations (R.H. McDowell, U.K. Patent 555,842, September 9, 1943). Probably because of a preoccupation with commercial pectin replacement in jams, jellies and gels which still persists (F.M. Rombouts, J.F. Thibault and C. Merrier, French Patent 8,307,203, 1983) there has been virtually no other commercial use of this interesting hydrocolloid complex. While others have commented academically on potential application based on chemical or physical characterization, there has been no reduction to practice of any use of beet pectin other than that of its use as a gel forming additive in fruit spreads.

Moreover, prior to the present invention, there was no process available which utilized a plug flow reactor to achieve hydrolytic extractions which provide a sugar beet pectin having properties which extended their scope of utility beyond jams, jellies and similar fruit spreads.

Accordingly, one or more of the following objects can be achieved by the practice of the present invention. It is an object of this invention to provide a sugar beet pectin extract having utility in comestibles. Another object of this invention is to provide a sugar beet pectin extract having characteristics not possessed by commercially available pectin products. A further object of this invention is to provide sugar beet pectins having applications in comestibles other than in fruit spreads. These and other objects will be readily apparent to those skilled in the art in the light of the teachings herein set forth.

EP-A-0102829 discloses a process for the production of biological polymeric materials. The process comprises:

- selecting plant material comprising a major proportion of parenchymal cells, said plant material comprising cellulose and hemicellulose;
- suspending the plant material in an aqueous medium;
- adjusting the pH of said suspension to a value either less than about 4.5 or more than about 10;
- heating said suspension to a temperature greater than about 125°C;
- maintaining said suspension at a temperature greater than 125°C for a period of time;
- subjecting said heated suspension to a degree of mechanical shearing sufficient to form a gruel having solid and liquid components, said temperature, time and degree of mechanical shearing being selected substantially to disassociate said hemicellulose from said cellulose without causing substantial degradation of said hemicellulose;
- separating said solid and liquid components; and
- recovering from said liquid component a material comprising at least a portion of said hemicellulose.

Utilities disclosed for the resulting materials include use as a viscosity and water loss control agent in well drilling fluids and use as an emulsifier for gums which adhere to polar materials such as paper and ceramics.

SUMMARY OF THE INVENTION

The present invention provides a sugar beet pectin as defined in claim 1 of the accompanying claims and a food or drug comestible as defined in claim 2. It also provides a process for imparting certain properties to a food or drug comestible as defined in claim 6.

Detailed Description of the Invention

It has been discovered that pectins derived from high temperature, controlled hydrolytic aqueous extraction of spent sugar beet pulp, provide a new class of hydrocolloids which have important application as functional additives and ingredients in comestibles other than gel functionality desired for jams and jellies. Specifically, beet pectins, prepared by this process, provide unusual emulsion stabilizing properties for flavor oils, vegetable oils and dairy products; a source of soluble dietary fiber which can be added to comestibles in sufficient amount to allow nutritional labeling claims without imparting undesirable properties to the food; a water binding or solids functionality in reduced caloric or dietetic foods where significant loss of texture or mouth feel results from replacement of sugar, dextrose or syrup solids with high intensity sweeteners; and a non-hydroscopic adhesive or film former for binding granulated or extruded food products and encapsulated or co-dried powders, respectively.

The method of the present invention relies on thermomechanical manipulation of the spent pulp under mildly acidic conditions whereby the hemicellulose complex becomes solubilized. In the case of sugar beet pulp the extracted complex is composed of high molecular weight polysaccharides whose composition is largely L-arabinose, D-galactose and D-galacturonic acid. The generic term for the dominant polysaccharide is "pectin". Pectin derived from sugar beet is very different from that isolated from other types of plant tissue such as citrus pulp. Beet pectin is highly acetylated and contains a moderate degree of feruloyl ester substitution. These relatively hydrophobic moieties coupled to extensive methyl esterification of D-galacturonic acid appear to generate lipophilic domains within an otherwise hydrophilic macromolecule. Ester functionality such as that to be found, in beet pectin ordinarily undergoes facile hydrolysis so that while limited hydrolysis is needed to elicit solubilization and extraction, extensive hydrolysis leading to loss of ester functionality is not usually desired.

Sugar beet pectin can be isolated in high yield by thermomechanical extraction of spent beet pulp under mildly acidic conditions. The preferred raw material is wet, pressed spent pulp. Since wet pulp is available only a short period during the year, dried pulp in the form of shreds or pellets may also be employed. Extraction temperatures in excess of 100°C are preferred with temperatures in the range of 120° to 160°C even more preferred. Relatively short residence times at these temperatures, typically under 5 minutes are preferred. Discharge to atmospheric pressure is achieved through a small diameter orifice with the jet impacting against a discharge plate. The high shear generated serves to enhance release of pectins and to disperse the processed tissue. The resulting puree containing dispersed cell walls, colloidal matter and solubilized pectins in an aqueous matrix is mechanically separated into a particulate fraction and a solubilized fraction -- particulate being all matter retained on a 500 mesh screen and the soluble fraction being all material passing through the 500 mesh screen. Yields of the soluble fraction are functions of the thermomechanical conditions, pH and method of solid/liquid separation employed. Yields are interrelated with desired properties of the pectin isolated. The protopectin material in beet is very complex and depending on the processing conditions more or less of certain fractions are released, admixed and accumulated from between and within the primary cell wall matrix. Therefore, depending on the method of extraction subtle or sometimes dramatic differences in the properties of the pectin may be observed.

Typically pH's in the range of pH 1.0 to pH 4.5 are effective in the preferred temperature range. Adjustment of pH prior to processing may be achieved with any strong mineral acid (H₂SO₄, H₃PO₄, HCl) with H₂SO₄ (SO₂ saturated water @ 20°C) preferred. Alternatively organic acids such as acetic, citric, malic or succinic acids may be used at the upper range of pH. Yields of soluble fraction may range from 25 to 60% w/w based on initial pulp solids. Further refining of the pectin may be desired to remove colloidal matter, reduce color, and de-ash. Drying is achieved by spray drying or thin film technique such as atmospheric drum drying.

According to a most preferred embodiment of the present invention, both hemicellulosic and cellulose components of sugar beet pulp or other parenchymal cell-containing plant material are isolated essentially simultaneously without substantial degradation of either component. Such may be accomplished through hydrolysis of spent sugar beet pulp (or other plant material containing parenchymal cells in high proportion) under conditions of moderate pH and high temperature for relatively short periods of time in association with physical shearing to improve dispersibility and pectin release.

According to one embodiment of this invention, the acidic extraction of sugar beet pulp is accomplished at pH's below 4.5 and preferably at pH's below 4.0 and even more preferable between 4.0 and 2.0. This acidic condition is maintained at a temperature above room temperature and for a period of time which is sufficiently substantial to liberate pectin and arabinogalactan from the sugar beet pulp but which is not sufficient to substantially degrade the same.

It is preferred that a temperature greater than 125°C be employed. It is more preferred to employ temperatures from

125°C to 250°C and even more preferred to employ temperatures between 140°C and 200°C. Still other preferred embodiments employ temperatures between 150°C and 180°C.

As will be appreciated by those skilled in the art reaction times which are sufficient to liberate hemicellulosic components from sugar beet pulp, pectins and arabinogalactans, will vary depending on the pH employed and the reaction temperature. It is preferred that reaction times less than 600 seconds be employed. It is still more preferred that reaction times less than 360 seconds be so employed with a still more preferred range being reaction times below 200 seconds. In general, reaction times effective to liberate the components will be greater than 15 seconds and preferably greater than 30 seconds.

According to one preferred embodiment, sugar beet pulp in aqueous slurry was acidified to a pH of about 3.5 with concentrated hydrochloric acid and hydrolyzed for approximately 40 seconds at 160°C. In accordance with another embodiment, sugar beet pulp was acidified to a pH of about 2.2 with HCl and hydrolyzed for about 170 seconds at about 165°C. As will also be understood by those skilled in the art, wide combinations of pH's, reaction time and temperature will be satisfactory for performing one or more of the embodiments of the present invention.

The isolation of the pectin components of sugar beet pulp or other parenchymal cell containing plant material may also be accomplished in strongly alkaline conditions. Thus, combinations of high (strongly basic) pH, relatively high temperature and relatively short reaction times may be so employed for such isolation. This combination of stringent pH at high temperatures for short times, however, results in the isolation of hemicellulosic components from such plant materials with substantial hydrolytic degradation, particularly with respect to saponification of ester functionality. In this regard, it is preferred that pH's greater, than 9.0 be employed for this hydrolysis. It is still more preferred to employ pH's between 9.5 and 12.0 and even more preferred to employ pH's from 10.5 to 11.0.

The times and temperatures which are useful for the alkaline hydrolysis in accordance with the present invention are similar to those which are useful for the acid hydrolysis. Thus, temperatures between 125°C and 250°C may be employed. It is preferred that temperatures between 140°C and 200°C be employed while still more preferred are temperatures between 150°C and 180°C.

Reaction times less than 600 seconds are preferred with reaction times less than 200 seconds being more preferred and reaction times from 30 to 120 seconds are still more preferred for certain embodiments. In general, reaction times greater than 15 seconds are needed.

The acid or alkaline hydrolysis of sugar beet pulp or other parenchymal cell-containing materials to isolate pectin and modified pectin components is greatly facilitated by the employment of physical shearing in connection herewith. It is preferred that extraction be conducted in conjunction with physical shearing to maximise the production of extractable components. In this regard, it is believed that the physical stressing or shearing assists in the disruption of the intracellular organization of sugar beet pulp and facilitates the liberation of the soluble polysaccharide complex. A wide variety of apparatus may be employed to effect such physical shear. Thus, in accordance with the preferred embodiment, a tubular reactor is employed which passes a slurry of parenchymal cell containing material at elevated temperature and pressure and at the desired pH through its length to one or more exit orifices. The slurry is then sprayed or "shot" through the orifice into a region of lesser pressure. This technique which is well known to those skilled in the art in terms of flash evaporation and other processes, provides a source of mechanical shear which is well suited to the practice of the present invention.

Other forms of mechanical shearing may also be employed such as an in-line blender or other device. With certain embodiments, shearing may be accomplished through ultrasonics or through any other technique which serves to effect substantial disruptions of the cellular organization.

It is most convenient to employ physical shearing simultaneously or shortly subsequent to the hydrolysis of sugar beet pulp or other plant material. Thus, the tubular reactor with "blow down" exit orifice is greatly preferred due to consideration of convenience and cost. It is also possible, however, to employ hydrolysis and physical shearing in separate steps. Thus, the plant material may be hydrolyzed under conditions of pH, time and temperature as hereinabove described, and stored under non-hydrolytic conditions prior to, for example, batchwise physical shearing in a blending device. Other modifications of the hydrolysis/physical shearing scheme will also be apparent to those skilled in the art.

A preferred reactor useful for the acidic or alkaline hydrolysis in accordance with one or more embodiments of the present invention comprises a tubular design. Thus, twelve stainless steel or other tubes having approximately (1.2cm) 1/2 inch inside diameter are parallel mounted through a 25 foot 7.62 m length of 12 inch (30.48 cm) inside diameter pipe and connected in series. Means are provided for introducing steam or other heating source into the outer jacket of the reactor in a controlled fashion so as to provide the desired temperature in the reaction tubes. An input pumping means is also provided for feeding a slurry of pH adjusted plant material into the reactor tubes. The discharge end of reactor tube series is provided with an orifice of small cross-sectional dimension typically 0.3-0.6 cm (1/8 to 1/4 inch). The orifice serves a dual purpose of maintaining internal pressure within the reactor tubes and of providing a high mechanical shearing effect upon the exit product stream when the same is forced therethrough.

In typical hydrolytic reactions in accordance with this invention, pulp is fed to the foregoing tubular reactor at head pressures ranging from 1.4-5.5 mPa (200 to 800 pounds per square inch). Superficial linear velocities at the exit orifice have been estimated from 10 to 100 meters per second. Thus, strong shear forces are encountered at the discharge

orifice. The product of the reactor is effectively "flushed" to atmospheric pressure after exit from the orifice and passed to subsequent processing operations.

While numerous reaction protocols may be employed by those skilled in the art for the practice of one or more embodiments of the present invention, in general, a slurry of plant material such as spent sugar beet pulp suspended in aqueous medium is adjusted to the desired pH, either acidic or alkaline and passed through a suitable reaction apparatus such as foregoing tubular reactor. The pH modified slurry is subjected to combinations of temperature and time at a pressure generally above atmospheric pressure. The material is then, in accordance with the preferred embodiment, passed through an exit orifice to atmospheric pressure to effect physical shearing. The resulting material may be viewed as having solid and liquid components. Separation of the solid and liquid material is generally followed by further processing.

As previously indicated, the sugar beet pectins prepared in accordance with the present invention possess properties which distinguish them from pectin previously known, particularly citrus pectin. In practice, the sugar beet pectins of the present invention are distinguished from citrus pectin, apple pectin, or other commercially available pectins, by one or more of the following properties:

- (a) low molecular weight;
- (b) highly acetylated;
- (c) many hydrophobic domains;
- (d) ferulic acid content of up to 3% w/w and preferably from 1 to 1.5 percent by weight; and
- (e) relatively low viscosity at 10% w/w or higher.

In accordance with another embodiment of the present invention, comestibles are provided comprised of sugar beet pectin, which have been found to be extraordinarily useful in a number of aspects of comestible production. Pectin is highly utilitarian for a wide variety of rheological uses and improvements. Such comestibles may be prepared in the form of dispersions, such as emulsions, foams, gels, doughs, and other forms. In this regard, the term "dispersion", as employed throughout the specification and appended claims, is defined generically to include emulsions, foams, gels, doughs, and the like.

Comestibles in accordance with the present invention may be prepared comprising yolk-containing aqueous emulsions, frozen confections, ice creams, ice milks, frozen toppings, mayonnaise, mayonnaise substitutes, thixotropic condiments, sauces, and a wide variety of other materials. Such comestibles may also be prepared comprising whips, and a whole host of dispersions, emulsions, gels, foams and other materials useful in the food and drug industries. The present invention also provides reconstitutable mixes for preparation of any of the foregoing materials.

A range of products will benefit by use of sugar beet pectin. Some of these are:

1. Dairy Products: Viscosity control, smooth texture, and fat mimicry are all enhanced with sugar beet pectin. Of special interest would be dairy products with textures such as yogurt, milk shakes, custards and ice creams. The structure building capability of sugar beet pectin would make possible low calorie formulas: the combination of low required levels and relatively low cost of sugar beet pectin would have significant cost advantages over the materials presently in use for such purposes. Ice creams are oil-in-water emulsions where the fat is provided by dairy cream: either the dairy proteins or added egg proteins provide emulsification and stabilization.

2. Pourable Dressings: Emulsion stability and flow/cling properties are all enhanced with sugar beet pectin. Moreover, greater reduction of oil should be easily attained for calorie reduced recipes than is presently possible, while maintaining desirable cling and mouthfeel lubricity.

The data of this study suggest that sugar beet pectin would make an excellent material on which to base no-oil salad dressing formulations. Levels of 1.0-5.0% (perhaps with approximately 0.1% of another hydrocolloid added to achieve a range of cling and mouthfeel properties) should be adequate for such purposes.

3. Puddings and Desserts: The texture of desserts is attained with a gelling agent. "Cold sets" are derived mostly from gelatin, "heat sets" mostly from starch. To get a range of yield values (the initial "bite," smoothness and "thickness") particulate "fillers" are added - these may be no-fat-dry-milk (NFDM) solids, microcrystalline cellulose (MCC), or emulsified fat droplets. Calorie reduction, texture manipulation, and cost reduction would be some of the advantages derived from the use of sugar beet pectin in dessert products.

4. Whipped Products: Stable aerated products are attained through the use of materials that produce a stabilizing elastic structure surrounding the air globule. Thus, in whipped cream, aggregated fat globules intermingle with protein complexes to provide an elastic structure about the fat globules. In meringues, the structure is provided by protein aggregates - heating at a sufficiently high temperature immobilizes the structure by producing an irreversibly entangled protein matrix on a film like encasement. Sugar beet pectin has great potential in stabilization of foamed products.

5. Meat Emulsions: These constitute another important class of food products. These emulsions use comminuted meat products and are essentially oil-in-water emulsions. The meat proteins that dissolve in the aqueous phase

behave as emulsifiers. Moreover, these proteins aid in the heat effected gelation process that normally is used to bind the product together as a cohesive unit. During the cooking process, loss of liquid can be extensive resulting in "yield loss" with aesthetically undesirable shrinkage. Sugar beet pectin helps to prevent this "yield loss."

6. **Confectioneries:** It would seem that the sugar beet pectin should find use in certain candies as a means to reduce calorie levels. The pectin will also make a good filler for low calorie cake icings.

7. **Spreads:** Spreads are either dispersions of solid particles in a liquid phase, an emulsion where either the fat/oil, or the aqueous phase, may be continuous, or a combination of both. Stabilization of these products is provided by emulsifiers and/or thickeners (e.g., hydrocolloids). High aqueous phase content is a means of providing low calorie products; however, achievement of adequate product stability becomes more difficult at high water contents. In order to function as a spread, spreadability is an important property and the product must, therefore, be malleable and soft, while thick enough in texture to retain shape. The sugar beet pectin is able to provide stable, creamy and spreadable dispersions when used in certain formulations.

The following example for the preparation of a useful pectin extract from sugar beet pulp should be considered exemplary and it will be appreciated by one skilled in the art that variations will be necessary or even desirable to achieve the wanted functionality. No additive pulp (pulp without added molasses, Steffen solids or other material) was ground to 30 mesh and hydrated by suspension in hot water at a solids content of 8-10% w/w. Sufficient H_2SO_4 was added to adjust the pH to 3.5. The swollen pulp-slurry was pumped through a proprietary plug flow reactor (manufactured by St. Lawrence Reactors, Ltd., Mississauga Ontario, Canada) at 155°C. The residence time was 40 seconds and the processed mass discharged to atmospheric pressure through a 0.3 cm (0.125 inch) diameter orifice against an impact disc. The resulting puree was converted into a liquid fraction containing 2.5 to 5.5% non-volatile solids and a sludge fraction employing a belt press (manufactured by Perrin Ltd., Toronto, Ontario, Canada). The sludge is discarded. The liquid fraction may be further refined by conventional centrifugation, filtration, decolorization, evaporation and spray dried. A preferred method involves centrifugation and concentration of the clarified supernatant by ultrafiltration. Subsequent dia-filtration employing a 30,000 Dalton cut-off membrane removes low molecular weight components prior to spray drying. The resulting powder is free flowing and non-hygroscopic, rehydrating on addition of water.

Typically the pectins obtained by the above procedure have a proximate analysis of 95% non-volatile matter containing 2-10% w/w ash on total solids. Refined material which has been decolorized is an off-white powder which hydrates to a pale yellow or amber solution depending on the concentration. The carbohydrate profile after acid and enzymatic hydrolysis is 40 to 75% w/w D-galacturonic acid eluting substances (D-rhamnose and D-galacturonic acid coelute in the HPLC system employed), 15 to 25% w/w L-arabinose and 5 to 10% w/w D-galactose. Acid insoluble matter on extensive acid hydrolysis (presumed to be feruloyl acid) is typically less than 3% and generally ranges 1 to 2% w/w. Protein content was estimated at 6.25 times Kjeldhal nitrogen and is typically under 1%. The degree of esterification, both acetyl and methyl ester) is highly variable depending on the degree of processing employed. For the above example, the degree of acetylation expressed as acetic acid content is 5.3% w/w and the methyl ester expressed as methanol is 3.8% w/w (determined by GC of an alkaline saponified sample). The rheology of a 10% solids solution likewise varies significantly depending on the degree of processing. Using a Bohlin 88 viscometer, (Bohlin Reologi Inc., East Brunswick, New Jersey), a 10% w/w solution appears somewhat pseudoplastic and displays a finite yield point employing the Casson model (for example, viscosity is 154 mPa.s at 1200 sec.⁻¹ versus 257 mPa.s at 1 sec.⁻¹ with an apparent yield point of 359 mPa). Apparent yield points have been obtained in excess of 10,000 mPa for sugar beet pectin preparations which have been enriched with the higher molecular weight components by ultra and dia-filtration.

The following examples are illustrative of the invention:

EXAMPLE 1: FLAVOR OIL EMULSION STABILIZATION

Brominated vegetable oil ($\sigma = 1.334$) and California orange oil ($\sigma = 0.844$) were obtained from Felton International, Inc. of Toronto, Canada. Purity GumTM (an octenyl succinate derivative of starch), manufactured by National Starch Company, was also obtained from Felton. Gum arabic was obtained from Sigma Chemical Company, St. Louis, Mo. Other chemicals were reagent grade from various chemical suppliers. A mixture of orange oil (5.05 parts by weight) and brominated vegetable oil (4.95 parts by weight) was prepared. The measured specific gravity was 1.046. Master emulsion bases were prepared - in tap water for Purity GumTM at 10% w/w pH 4.36, gum arabic at 5% w/w pH 5.46 and sugar beet pectin (HC-223) at 5% w/w pH 4.5 containing 0.1% w/w sodium benzoate. A 10% w/w flavor oil in water emulsion was prepared by homogenization of a 250 g mixture (225 g base and 25 g oil) for six minutes at 10,000 rpm employing an Ultra TuraxTM T50 homogenizer with a G40F generator assembly (manufactured by IKA Laboratories of Staufen, West Germany). The temperature rise did not exceed 47°C and the homogenates were quickly cooled to room temperature. Examination under the light microscope indicated all homogenates contained a dispersed phase under 5u and most droplets were under 2u. All three homogenates appeared similar in particular size distribution. A master beverage base was prepared containing:

240g sucrose
 20g citric acid monohydrate
 2.0g sodium benzoate
 1738g water

The pH of the beverage base @ 20°C was 2.48 and the $\sigma = 1.052$. An aliquot of each master emulsion (3.1 ml) was introduced into 200 ml of the beverage base in a capped 250 ml Erlenmeyer flask and well dispersed by shaking. All three emulsions produced a milky white, homogeneous dispersion on mixing with the beverage base. After 24 hours at 20°C, both the master and beverage emulsions were stable and homogeneous. The pectin stabilized emulsion was indistinguishable from that of gum arabic and modified starch. After three months some gravitational sedimentation occurred in all three emulsions, both master and beverage. The homogenisation device either evaporates away sufficient volatile orange oils (or they become solubilized over time) to cause the density of the oil mixture to increase causing perhaps the larger particle population to gravitationally settle. In all three cases, the settled particles did not coalesce and were completely redispersed by simply swirling or shaking the container. While in practice this phenomenon would not be desirable (and would be eliminated by proper formulation and reduction in the size of the oil droplet population), it is a severe test for emulsion stability in that the settled emulsion droplets are in intimate contact yet do not coalesce.

EXAMPLE 2: CARBONATED BEVERAGES

Carbonated beverages in which a high intensity sweetener was substituted for sucrose were prepared from flavor emulsions stabilized with sugar beet pectin. A control containing 0.1% w/w CMC, which is commonly employed as an agent to restore "mouth feel" lost by the removal of sucrose solids, was compared with a beverage containing only the pectin carried over from the master emulsion. In addition, a beverage was prepared containing relatively high amounts of pectin at 2% w/w, demonstrating that a highly palatable "high fiber", carbonated beverage could be formulated which would have very low caloric content, yet deliver a high amount of soluble fiber per 12 oz. serving (7g soluble vegetable fiber).

Sucralose™, a trichloroglactosucrose derivative, was obtained from Redpath Industries, Toronto, Canada, and prepared as a 10% w/w aqueous solution. Low viscosity CMC (sodium carboxy methyl cellulose), was obtained from Sigma Chemical Company, St. Louis, Missouri, and the flavor/weighting oils from sources identified in the previous example. All other reagents were certified, or food grade obtained through commercial vendors.

The master flavor emulsions were prepared by homogenizing a 10% w/w oil mixture $\sigma = 1.0$ (1.146 parts orange oil, $\sigma = 0.844$ with 0.854 parts BVO, $\sigma = 1.33$) containing 10% w/w sugar beet pectin. Initial homogenization was performed by high speed dispersion employing a rotor/stator device at 20,000 rpm, Omni International, Waterbury, Connecticut, and a secondary homogenization with an ultrasonic dismembrator obtained from Fisher Scientific Company, Chicago, Illinois. Table I lists the composition of the final beverages.

TABLE I

	CMC Expt.	Control	High Fiber Expt.
Water	970.40g	971.49g	951.49g
Sucralose™ 10% w/w	1.29g	1.29g	1.29g
Citric Acid monohydrate 50% w/w	5.44g	5.44g	5.44g
Sodium Citrate dihydrate 25% w/w	4.42g	4.42g	4.42g
Sodium Benzoate 15% w/w	1.76g	1.76g	1.76g
CMC	1.09g	--	--
Sugar Beet Pectin (247/248)	--	--	20.0g
Flavor Emulsion 10% w/w	15.6g	15.6g	15.6g
	<u>1000.0</u>	<u>1000.0</u>	<u>1000.0</u>

Carbonation was achieved by addition of 2.5g dry ice to 200 g of beverage in a standard, long neck clear glass beer bottle (total internal volume 382 ml) and capping. After sixteen hours, the CO₂ equilibrated without leaking around the

cap seal producing a well carbonated beverage on uncapping.

After ten days, all three beverages displayed excellent emulsion stability with no visual evidence of ringing or setting. On opening, the CMC containing beverage was undiscernible by taste and mouth feel from the control containing pectin carried over in the master flavor emulsion. Note the approximate 60x dilution of the 10% w/w pectin in the emulsion results in a 0.17% w/w pectin component in both the control and CMC (0.1% w/w) containing beverage which indicates that pectin is dominating the mouth feel of both beverages. The 2% w/w pectin beverage had a pleasant, but pronounced body, and appeared to slightly mute the orange flavor indicating its potential use as an agent controlling flavor release in beverages or other comestibles. All three types of beverage showed no evidence of degeneration after storage at room temperature, or refrigerated at 4°C for four months. A small amount of emulsion settling was observed, but no coalescence was observed and the emulsion was easily restored by gentle agitation.

EXAMPLE 3: PUMPABLE VEGETABLE OIL SPREADS

The objective of this example is to produce a reduced caloric margarine spread that is pumpable and can be conveniently dispensed from a container by squeezing or metering via the "toothpaste or lotion" type pump container. It has been found possible to form a stable high oil content (>50% oil) in water emulsion with beet pectin whereby the emulsion is formed at a temperature above the melting point of the oil/fat phase. The resulting emulsion is then cooled to a temperature below the melting point of the oil/fat phase but above the freezing point of the continuous phase to produce a hardened non-coalescing suspension of the oil/fat phase.

A 175g aliquot of ordinary margarine (non-salted 80%, hydrogenated soya oil based, containing 40% polyunsaturates) was added to 105g of an aqueous sugar beet pectin syrup (HC-223, 13.6 brix, pH 4.5) and heated to 50°C. The binary mixture was homogenized for three minutes on the Ultra Turax at 10,000 rpm. The final calculated composition of the homogenate was 5.1% w/w beet pectin solids (13.6% w/w based on aqueous continuous phase) 32.3% w/w water and 62.5% w/w margarine. The viscous homogenate was poured into a "hand lotion pump" container and placed in the refrigerator overnight at 4°C.

On examination the next day the gel-like homogenate was pumpable and showed no signs of coalescence. After 2.5 months, the mixture showed no visible change and was pumpable yielding a creamy white gel that is readily spreadable. It is clear that the pectin emulsion under these conditions results in a gel-type structure, which although sufficient in strength to prevent buoyant creaming of the lighter fat/oil phase, is easily broken to allow flow to occur.

EXAMPLE 4: INCORPORATION OF SOLUBLE FIBER INTO WHITE BREAD

It has been found that the pectin isolated from sugar beet can be added to breads in significant quantity without changing the apparent dough handling properties or appearance and texture of the final baked bread. The following recipes were used:

	Control Bread	Experimental Bread
Generic bleached flour (3c.)	420g	420g
Salt (1 tsp.)	9.0g	9.0g
Sugar (1 tblsp.)	12.0g	12.0g
Scalded skim milk (1 c.)	233.0g	
Cooled to 40°C (1/4 c.)	56.0g	
Beet pectin sol. @ 12% bx. (1 c.)		260.0g
Warmed to 40°C (1/4 c.)		62.7
1 pkg. yeast	7.0g	7.0g
Margarine (2 tblsp.)	28.0g	28.0g

The yeast used was Fleischman's Rapid Rise™ and other ingredients generic grocery products. All ingredients with the exception of the flour were well mixed on a Sunbeam Mixmaster™. Flour was gradually added employing dough hooks and mixed for four minutes at high speed. The resulting dough was removed and hand kneaded for a further four minutes. Additional flour was added during hand kneading to control the sticky character of the resulting doughs in

amounts of 27.1g and 30.4 g for the control and experimental doughs, respectively. The doughs were allowed to rise at 80°F (26.6°C) in a high humidity environment - first rise was 1 hour and 15 minutes for both; second rise was 2 hours 10 minutes for control and 1 hour 50 minutes for the experimental loaf. Both breads were baked at 177°C (350°F) for 45 minutes.

The baked loaves were very similar in loaf volume and weighed 627.5g (control) and 670.6g (experimental). The difference is largely a consequence of the added pectin solids and the slightly larger addition of flour during kneading. The amount of beet pectin added amounts to 38 grams or nearly 9% based on flour content. If a 20 slice loaf is assumed, the soluble dietary fiber content is approximately 2g/slice and is achieved without significant change in texture, color, taste or quality in general of the final loaf.

EXAMPLE 5: ENCAPSULATION OF OLEAGINOUS MATERIALS -VITAMIN E

Two types of beet pectin were prepared. The first (HC-237), was prepared employing an 86 second reaction time at pH3.5, 160°C, using never dried spent pulp. It was refined by centrifugation, concentrated and dialyzed by microfiltration against a 0.45 μ highly anionic membrane to approximately 15 brix. It represents a low viscosity pectin giving an apparent yield point of 13 mPa and a viscosity of 27 mPa.s at 1200 sec⁻¹ at a concentration of 10% w/w, pH 4.5. The second preparation HCP268/274 was prepared by ultrafiltration (30,000 Dalton membrane) of the microfiltration permeate from a standard mild extraction, pH3.5, 38 sec at 160°C. It represents a low molecular weight population of pectins normally discarded during membrane based processing, and forms thickened, but pourable syrups at 40% solids. Both pectin preparations are excellent film formers.

Two types of systems are commonly employed when spray drying is the means of encapsulation. The first employs an emulsion stabilizing agent, typically a hydrophobically modified starch such as Amiogum™, in conjunction with a high solids carrier which provides film forming function such as a 10 DE maltodextrin. The second employs a single agent as both stabilizer and carrier, such as gum arabic or Capsul™, an octenylsuccinate derivative of hydrolyzed starch. Each of the two pectin preparations described above represents one of the two types of encapsulation systems - HC237, a natural stabilizer, can be supplemented with an inexpensive maltodextrin carrier similar to Amiogum™, or HC-P268/274, provides an all natural, high solids combination stabilizer/carrier similar to Capsul™ or gum arabic.

System 1: A 40% w/w total solids emulsion of -dl tocopherol acetate (Vitamin E), obtained from Hoffman La Roche, Nutley, New Jersey, was prepared by homogenization of one liter for 15 minutes of a 19.7% w/w neat Vitamin E oil in a 20.9% w/w pectin syrup (HC-P263/274) pH 3.4 at 66°C employing a rotor/stator type homogenizer (Model CJ4B, ARDE Berinco, Mahwah, N.J.). The homogenate was then spray dried in a Bowen Model JBE-926 laboratory sprayer employing an inlet temperature of 400°C and an outlet temperature of 260°C. The resulting product was a light tan, free flowing powder with a bulk density of 0.27 and particle size distribution largely between 200 and 600 μ (70% 600-425 μ) and assayed by GC at 47.6% vitamin E on an "as is" basis, or on a "dry basis" (12 hrs. at 80°C) was 48.5% dry basis. Calculated content is 48% Vitamin E.

System 2: A 57% w/w total solids emulsion was prepared by homogenizing sufficient Vitamin E oil into a 12.9% w/w pectin syrup (HC 237), containing 27.1% w/w maltodextrin to a final concentration of 28.6% w/w oil, 19.4% w/w maltodextrin and 9.2% w/w pectin. The temperature of the resulting homogenate was 65°C and the pH 3.9. Sufficient water was added (175 ml to 980g of homogenate) to thin the mixture for spray drying at a final solids content of approximately 50% w/w. Homogenization and spray drying parameters were similar to those described in System 1. A free flowing, off-white powder, with a specific gravity of 0.26 was obtained. The majority of the particles were in the 200-600 μ range (71% 425-600 μ). The Vitamin E content was determined to be 42.7% on an "as is" basis, and on a "dry basis" was 43.5% dry basis. The expected content is 50% Vitamin E.

EXAMPLE 6: HYPOCHOLESTEROLEMIC RESPONSE IN RAT TO DIETARY CHOLESTEROL CHALLENGE IN THE PRESENCE OF BEET PECTIN

While it is acknowledged that substantial difference exists between rat and human metabolism, the rat model is considered to be a potential indicator of agents influencing cholesterol transport, storage and metabolism in mammals.

The rat model is particularly interesting because this animal is believed to have very little control over cholesterol absorption in the gastrointestinal tract. Alternatively, the rat maintains serum cholesterol and related circulating conjugate levels very well with the result that excess is accumulated by the liver. Therefore, liver cholesterol loading is believed to be a measure of the effectiveness of agents incorporated into the diet, which influence reabsorption of secreted cholesterol (bile acids) and dietary cholesterol (ingested).

Male Wistar rats were purchased from the Charles River Breeding Labs, Wilmington, Mass. Four groups of six rats were acclimated for seven days on a standard semi-purified diet manufactured by Dyets Inc., Bethlehem, Pa. to a specification similar to that employed in conventional nutritional studies reported by others (Kritchevsky, D. et al, "Serum & Liver Lipids of Rats Fed Coco Butter, Corn Oil, Palm Kernel Oil, Coco Oil and Cholesterol", Nutrition Research, Vol. 8, pgs. 287-294 (1988)). After the acclimation period, the four groups of rats were separated and received the following

diets.

- Diet B - basal diet (control group).
 Diet BC - basal diet and 5% cholesterol.
 Diet 5F-BC - basal diet and 5% cholesterol + 5% sugar beet pectin.
 Diet 10F-BC - basal diet + 5% cholesterol + 10% sugar beet pectin.

The sugar beet pectin preparation had been prepared by a mild acidic extraction - pH 3.5, 38 sec. residence time at 160°C using dried spent pulp. It had been clarified by centrifugation, concentrated and dialyzed by microfiltration, and spray dried to a fine, light tan powder. The rheological profile of a 10% w/w solids solution at pH 4.5 gave an apparent yield point of 2300 mPa and a viscosity at 1200 sec⁻¹ of 243 mPa.s indicating a moderately viscous fluid. The degree of methyl esterification based on the galacturonic acid content was 80%. It was blended into the basal diet in powdered form.

After 21 days the rats were sacrificed. Serum was taken for analysis of cholesterol and triglycerides. The liver was examined for total and free cholesterol and triglycerides. Key organ weights and total subject weights were recorded. Table 2 summarizes the results. No animals showed any effects of nutritional distress. The fiber diet did not affect body weight, but led to smaller livers (both in real weight or percentage of body weight).

TABLE 2

	Diet B	Diet BC	Diet 5F-BC 5% Fiber	Diet 10F-BC 10% Fiber
Animal Starting wt.(g)	185±4.4	185±3.4	185±5.6	185±5.4
End wt. (g)	332±11.8	327±7.4	318±9.8	322±9.1
D wt. (g)	147±7.7	142±6.5	133±7.1	137±5.3
Liver wt. (g)	9.7±0.57	13.0±0.67	11.9±0.59	11.5±0.59
Rel. liver wt.(%)	2.91±0.08	3.96±0.14	3.74±0.10	3.59±0.03
Serum (mg/dl)				
Total Cholesterol	5.4±2.02	60±1.27	57±1.79	55±1.91
% HDL Cholesterol	51.8±1.86	49.6±1.01	48.9±2.18	49.3±1.42
Triglycerides	42.7±1.8	42.3±1.6	43.3±2.6	44.7±3.1
Liver Analysis (g)/100g				
Total Cholesterol	0.674±0.016	2.54±0.32	2.29±0.22	2.15±0.21
Free Cholesterol	0.250±0.015	0.476±0.018	0.475±0.007	0.439±0.033
% Ester Cholesterol	62.9±1.65	80.0±2.31	78.4±1.93	78.4±2.88
Triglycerides	2.526±0.43	7.82±0.75	7.41±0.77	7.36±0.83
Serum cholesterol (pool) (mg)	5.4±0.33	5.8±0.20	5.5±0.23	5.3±0.24
Liver Cholesterol (mg)	65.5± 5.0	331.1±47.9	272.4±29.6	243.0±20.9
Serum + Liver Cholesterol (mg)	70.9±5.2	337.0±48.1	276.0±29.7	248.4±20.8

As expected, sugar beet pectin had little effect on reduction of serum lipids, but did cause reduction of 10 to 15% in total liver cholesterol. The serum plus liver pools in the 5% and 10% pectin groups were reduced by 18 and 26%, respectively, compared to the control cholesterol group. Based on these studies, sugar beet pectin appears to have a low, but significant, effect on cholesterol absorption in the rat model. This indicates it may be effective as a soluble dietary fiber supplement in human diets, augmenting or replacing other fiber ingredients to provide an important dietary function without severe organoleptic distress of foods into which it is incorporated.

Claims

Claims for the following Contracting States : AT, BE, CH, DE, DK, FR, GB, IT, LI, LU, NL, SE

- 5 1. Sugar beet pectin which is retained by a 30,000 Dalton ultra-filtration membrane and contains at least 30% and not more than 60% by weight of galacturonic acid, said sugar beet pectin being preparable by:

10 suspending sugar beet plant material in an aqueous medium to form a suspension;
adjusting the pH of said suspension to a value less than 4.5 or greater than 9.0;
maintaining said suspension at a temperature greater than 125°C for from 15 to 600 seconds;
subjecting said suspension to mechanical shearing; and
isolating said sugar beet pectin from said suspension.

- 15 2. A food or drug comestible, other than fruit spreads, having at least one of the following properties;

16 (a) reduced caloric content;
17 (b) reduced fat content;
18 (c) improved texture;
19 (d) improved flavour release; and
20 (e) improved mouth feel

21 said comestible being comprised of at least one first material in at least one second material, and at least some sugar beet pectin as claimed in claim 1 in an amount sufficient to impart at least one of said properties to said comestible.

- 25 3. The comestible of claim 2, which a food product.

- 26 4. The comestible of claim 3, wherein said food product is at least one member selected from the group consisting of emulsions, foams, batters and doughs.

- 30 5. The comestible of claim 2, which is a drug.

- 31 6. A process for imparting to a food or drug comestible, other than fruit spreads, the following properties:

35 (a) reduced caloric content;
(b) reduced fat content; or
(c) improved texture;
(d) improved flavour release; and
40 (e) improved mouth feel

41 said comestible being comprised of at least one first material in at least one second material, said process comprising mixing at least some sugar beet pectin of claim 1 with said food or drug comestible in an amount sufficient to impart at least one of said properties to said comestible.

- 45 7. Sugar beet pectin according to claim 1 that is partially hydrolysed and dissolves in water.

- 46 8. A composition comprising partially hydrolysed sugar beet pectin according to claim 7 dissolved in water.

- 50 9. A process for making a sugar beet pectin which is retained by a 30,000 Dalton ultra-filtration membrane and contains at least 30% and not more than 60% by weight of galacturonic acid, said process comprising the steps of:

51 suspending sugar beet plant material in an aqueous medium to form a suspension;
adjusting the pH of said suspension to a value less than 4.5 or greater than 9.0;
maintaining said suspension at a temperature greater than about 125°C for from 15 to 600 seconds;
55 subjecting said suspension to mechanical shearing; and
isolating said sugar beet pectin from said suspension.

Claims for the following Contracting State : ES

1. Process for making a sugar beet pectin which is retained by a 30,000 Dalton ultra-filtration membrane and contains at least 30% and not more than 60% by weight of galacturonic acid, said process comprising the steps of:

suspending sugar beet plant material in an aqueous medium to form a suspension;
adjusting the pH of said suspension to a value less than 4.5 or greater than 9.0;
maintaining said suspension at a temperature greater than 125°C for from 15 to 600 seconds;
subjecting said suspension to mechanical shearing; and
isolating said sugar beet pectin from said suspension.

2. A process according to claim 1, wherein the sugar beet pectin is partly hydrolysed and dissolves in water.

3. A process for imparting to a food or drug comestible, other than fruit spreads, the following properties:

- (a) reduced caloric content;
- (b) reduced fat content; or
- (c) improved texture;
- (d) improved flavour release; and
- (e) improved mouth feel

said comestible being comprised of at least one first material in at least one second material, said process comprising mixing at least some sugar beet pectin of claim 1 or 2 with said food or drug comestible in an amount sufficient to impart at least one of said properties to said comestible.

4. The process of claim 3, wherein said food product is at least one member selected from the group consisting of emulsions, foams, batters and doughs.

5. The process of claim 2, wherein the product is a drug.

Claims for the following Contracting State : GR

1. Sugar beet pectin which is retained by a 30,000 Dalton ultra-filtration membrane and contains at least 30% and not more than 60% by weight of galacturonic acid, said sugar beet pectin being preparable by:

suspending sugar beet plant material in an aqueous medium to form a suspension;
adjusting the pH of said suspension to a value less than 4.5 or greater than 9.0;
maintaining said suspension at a temperature greater than 125°C for from 15 to 600 seconds;
subjecting said suspension to mechanical shearing; and
isolating said sugar beet pectin from said suspension.

2. A food comestible, other than fruit spreads, having at least one of the following properties;

- (a) reduced caloric content;
- (b) reduced fat content;
- (c) improved texture;
- (d) improved flavour release; and
- (e) improved mouth feel

said comestible being comprised of at least one first material in at least one second material, and at least some sugar beet pectin as claimed in claim 1 in an amount sufficient to impart at least one of said properties to said comestible.

3. The comestible of claim 2, which a food product.

4. The comestible of claim 3, wherein said food product is at least one member selected from the group consisting of emulsions, foams, batters and doughs.

5. A process for imparting to a food or drug comestible, other than fruit spreads, the following properties:

- (a) reduced caloric content;
- (b) reduced fat content; or
- (c) improved texture;
- (d) improved flavour release; and
- (e) improved mouth feel

said comestible being comprised of at least one first material in at least one second material, said process comprising mixing at least some sugar beet pectin of claim 1 with said food or drug comestible in an amount sufficient to impart at least one of said properties to said comestible.

6. Sugar beet pectin according to claim 1 that is partially hydrolysed and dissolves in water.

7. A composition comprising partially hydrolysed sugar beet pectin according to claim 7 dissolved in water.

Patentansprüche

Patentansprüche für folgende Vertragsstaaten : AT, BE, CH, DE, DK, FR, GB, IT, LI, LU, NL, SE

1. Zuckerrübenpektin, das durch eine 30.000 Dalton Ultrafiltrationsmembran zurückgehalten wird und mindestens 30 Gew.-% und nicht mehr als 60 Gew.-% Galacturonsäure enthält, wobei das Zuckerrübenpektin folgendermaßen herstellbar ist:

Suspensionieren von Zuckerrübenpflanzenmaterial in einem wässrigen Medium zur Herstellung einer Suspension;

Einstellen des pH-Werts dieser Suspension auf einen Wert kleiner als 4,5 oder größer als 9,0;

Halten dieser Suspension bei einer Temperatur von mehr als 125 °C für einen Zeitraum von 15 bis 600 Sekunden;

Ausüben mechanischer Scherkräfte auf diese Suspension;

Isolieren des Zuckerrübenpektins aus der Suspension.

2. Nahrungsmittel- oder medizinische Eßware mit Ausnahme von Fruchtaufstrichen, die wenigstens eine der folgenden Eigenschaften aufweist:

- a) verminderter Kaloriengehalt;
- b) verminderter Fettgehalt;
- c) verbesserte Textur;
- d) verbesserte Aromafreisetzung;
- e) verbessertes Mundgefühl

wobei die Eßware aus wenigstens einem ersten Material in wenigstens einem zweiten Material besteht, und aus wenigstens etwas Zuckerrübenpektin nach Anspruch 1 in einer Menge, die ausreichend ist, um der Eßware wenigstens eine der genannten Eigenschaften zu verleihen.

3. Eßware nach Anspruch 2, die ein Nahrungsmittel ist.

4. Eßware nach Anspruch 3, bei der das Nahrungsmittel wenigstens ein Mitglied ausgewählt aus der Gruppe bestehend aus Emulsionen, Schäumen, geschlagenen Teigen und Teigen ist.

5. Eßware nach Anspruch 2, die ein Arzneimittel ist.

6. Verfahren, um einer Nahrungsmittel- oder medizinischen Eßware mit Ausnahme von Fruchtaufstrichen die nachfolgenden Eigenschaften zu verleihen:

- a) verminderter Kaloriengehalt;
- b) verminderter Fettgehalt;

- c) verbesserte Textur;
- d) verbesserte Aromafreisetzung;
- e) verbessertes Mundgefühl

wobei die Eßware aus wenigstens einem ersten Material in wenigstens einem zweiten Material besteht, wobei das Verfahren den Schritt des Mischens von wenigstens etwas Zuckerrübenpektin nach Anspruch 1 mit der Nahrungsmittel- oder medizinischen Eßware in einer Menge, die ausreichend ist, um der Eßware wenigstens eine der genannten Eigenschaften zu verleihen, aufweist.

7. Zuckerrübenpektin nach Anspruch 1, das teilweise hydrolysiert ist und sich in Wasser löst.

8. Zusammensetzung, die teilweise hydrolysiertes Zuckerrübenpektin nach Anspruch 7 gelöst in Wasser enthält.

9. Verfahren zum Herstellen eines Zuckerrübenpektins, das durch eine 30.000 Dalton Ultrafiltrationsmembran zurückgehalten wird und wenigstens 30 Gew.-% und nicht mehr als 60 Gew.-% Galacturonsäure enthält, das die folgenden Schritte aufweist:

Suspendieren von Zuckerrübenpflanzenmaterial in einem wäßrigen Medium zur Herstellung einer Suspension;

Einstellen des pH-Werts dieser Suspension auf einen Wert kleiner als 4,5 oder größer als 9,0;

Halten dieser Suspension bei einer Temperatur von mehr als 125 °C für einen Zeitraum von 15 bis 600 Sekunden;

Ausüben mechanischer Scherkräfte auf diese Suspension;

Isolieren des Zuckerrübenpektins aus der Suspension.

Patentansprüche für folgenden Vertragsstaat : ES

1. Verfahren zum Herstellen eines Zuckerrübenpektins, das durch eine 30.000 Dalton Ultrafiltrationsmembran zurückgehalten wird und wenigstens 30 Gew.-% und nicht mehr als 60 Gew.-% Galacturonsäure enthält, das die folgenden Schritte aufweist:

Suspendieren von Zuckerrübenpflanzenmaterial in einem wäßrigen Medium zur Herstellung einer Suspension;

Einstellen des pH-Werts dieser Suspension auf einen Wert kleiner als 4,5 oder größer als 9,0;

Halten dieser Suspension bei einer Temperatur von mehr als 125 °C für einen Zeitraum von 15 bis 600 Sekunden;

Ausüben mechanischer Scherkräfte auf diese Suspension;

Isolieren des Zuckerrübenpektins aus der Suspension.

2. Verfahren nach Anspruch 1, bei dem das Zuckerrübenpektin teilweise hydrolysiert ist und sich in Wasser löst.

3. Verfahren, um einer Nahrungsmittel- oder medizinischen Eßware mit Ausnahme von Fruchtaufstrichen die nachfolgenden Eigenschaften zu verleihen:

- a) verminderter Kaloriengehalt;
- b) verminderter Fettgehalt;
- c) verbesserte Textur;
- d) verbesserte Aromafreisetzung;
- e) verbessertes Mundgefühl

wobei die Eßware aus wenigstens einem ersten Material in wenigstens einem zweiten Material besteht, wobei das

Verfahren den Schritt des Mischens von wenigstens etwas Zuckerrübenpektin nach Anspruch 1 oder 2 mit der Nahrungsmittel- oder medizinischen Eßware in einer Menge, die ausreichend ist, um der Eßware wenigstens eine der genannten Eigenschaften zu verleihen, aufweist.

- 5 4. Verfahren nach Anspruch 3, bei dem das Nahrungsmittelprodukt wenigstens ein Mitglied ausgewählt aus der Gruppe bestehend aus Emulsionen, Schäumen, geschlagenen Teigen und Teigen ist.
5. Verfahren nach Anspruch 2, bei dem das Produkt ein Arzneimittel ist.

10 **Patentansprüche für folgenden Vertragsstaat : GR**

1. Zuckerrübenpektin, das durch eine 30.000 Dalton Ultrafiltrationsmembran zurückgehalten wird und mindestens 30 Gew.-% und nicht mehr als 60 Gew.-% Galacturonsäure enthält, wobei das Zuckerrübenpektin folgendermaßen herstellbar ist:

15 Suspendieren von Zuckerrübenpflanzenmaterial in einem wäßrigen Medium zur Herstellung einer Suspension;

20 Einstellen des pH-Werts dieser Suspension auf einen Wert kleiner als 4,5 oder größer als 9,0;

Halten dieser Suspension bei einer Temperatur von mehr als 125 °C für einen Zeitraum von 15 bis 600 Sekunden;

25 Ausüben mechanischer Scherkräfte auf diese Suspension;

Isolieren des Zuckerrübenpektins aus der Suspension.

2. Nahrungsmittelleßware mit Ausnahme von Fruchtaufstrichen, die wenigstens eine der folgenden Eigenschaften aufweist:

- a) verminderter Kaloriengehalt;
- b) verminderter Fettgehalt;
- c) verbesserte Textur;
- d) verbesserte Aromafreisetzung;
- 35 e) verbessertes Mundgefühl

wobei die Eßware aus wenigstens einem ersten Material in wenigstens einem zweiten Material besteht, und aus wenigstens etwas Zuckerrübenpektin nach Anspruch 1 in einer Menge, die ausreichend ist, um der Eßware wenigstens eine der genannten Eigenschaften zu verleihen.

- 40 3. Eßware nach Anspruch 2, die ein Nahrungsmittel ist.
4. Eßware nach Anspruch 3, bei der das Nahrungsmittel wenigstens ein Mitglied ausgewählt aus der Gruppe bestehend aus Emulsionen, Schäumen, geschlagenen Teigen und Teigen ist.
- 45 5. Verfahren, um einer Nahrungsmittel- oder medizinischen Eßware mit Ausnahme von Fruchtaufstrichen die nachfolgenden Eigenschaften zu verleihen:
 - a) verminderter Kaloriengehalt;
 - b) verminderter Fettgehalt;

 - 50 e) verbessertes Mundgefühl

55 wobei die Eßware aus wenigstens einem ersten Material in wenigstens einem zweiten Material besteht, wobei das Verfahren den Schritt des Mischens von wenigstens etwas Zuckerrübenpektin nach Anspruch 1 mit der Nahrungsmittel- oder medizinischen Eßware in einer Menge, die ausreichend ist, um der Eßware wenigstens eine der genannten Eigenschaften zu verleihen, aufweist.

6. Zuckerrübenpektin nach Anspruch 1, das teilweise hydrolysiert ist und sich in Wasser löst.
7. Zusammensetzung, die teilweise hydrolysiertes Zuckerrübenpektin nach Anspruch 6 gelöst in Wasser enthält.

5 Revendications

Revendications pour les Etats contractants suivants : AT, BE, CH, DE, DK, FR, GB, IT, LI, LU, NL, SE

1. Un procédé de préparation d'une pectine de betterave qui est retenue par une membrane d'ultra-filtration présentant un seuil de coupure correspondant à 30 000 Dalton qui contient au moins 30% et pas plus de 60% en poids d'acide galacturonique, le procédé comprenant les étapes de:

- mise en suspension du matériel végétal de betterave dans un milieu aqueux pour former une suspension;
- ajustement du pH de ladite suspension à une valeur inférieure à 4,5 ou supérieure à 9,0;
- maintien de la suspension à une température supérieure à 125°C pendant une période de 15 à 600 secondes;
- cisaillement mécanique de ladite suspension; et
- isolement de ladite pectine de betterave à partir de ladite suspension.

2. Un produit ou médicament comestible, autre que les produits à tartiner à base de fruits, présentant au moins l'une des propriétés suivantes:

- (a) teneur réduite en calorie;
- (b) teneur en graisse réduite;
- (c) texture améliorée;
- (d) libération d'arome amélioré; et
- (e) propriété gustative améliorée;

ledit comestible comprenant au moins un premier matériau dans au moins un second matériau, et comprenant au moins de la pectine de betterave selon la revendication 1 en une quantité suffisante pour conférer au moins l'une desdites propriétés audit produit comestible.

3. Le produit comestible selon la revendication 2, qui correspond à un produit alimentaire.
4. Le produit comestible selon la revendication 3, dans lequel ledit produit alimentaire est au moins un élément sélectionné dans le groupe consistant en: émulsions, mousses, pâte à crêpes et à beignets et pâtes à pétrir.

5. Le produit comestible selon la revendication 2, qui est un médicament.

6. Un procédé pour conférer à un produit comestible ou un médicament, autre que les produits à tartiner à base de fruits, les propriétés suivantes:

- (a) teneur réduite en calorie;
- (b) teneur en graisse réduite; ou
- (c) texture améliorée;
- (d) libération d'arome amélioré; et
- (e) propriété gustative améliorée;

ledit produit comestible étant composé d'au moins un premier matériau dans au moins un second matériau, ledit procédé comprenant le mélange d'au moins de la pectine de betterave selon la revendication 1 avec ledit produit comestible ou le médicament en une quantité suffisante pour conférer au moins l'une desdites propriétés audit produit comestible.

7. Pectine de betterave selon la revendication 1, qui est partiellement hydrolysée et dissoute dans l'eau.
8. Une composition comprenant une pectine de betterave partiellement hydrolysée selon la revendication 7 dissoute dans de l'eau.
9. Un procédé de préparation d'une pectine de betterave qui est retenue par une membrane d'ultra-filtration présentant un seuil de coupure correspondant à 30 000 Dalton et qui contient au moins 30% et pas plus de 60% en poids

d'acide galacturonique, ledit procédé comprenant les étapes de:

- mise en suspension du matériel végétal de betterave dans un milieu aqueux pour former une suspension;
- ajustement du pH de ladite suspension à une valeur inférieure à 4,5 ou supérieure à 9,0;
- maintien de la suspension à une température supérieure à 125°C pendant une période de 15 à 600 secondes;
- cisaillement mécanique de ladite suspension; et
- isolement de ladite pectine de betterave à partir de ladite suspension.

Revendications pour l'Etat contractants suivant : ES

1. Un procédé de préparation d'une pectine de betterave qui est retenue par une membrane d'ultra-filtration présentant un seuil de coupure correspondant à 30 000 Dalton et qui contient au moins 30% et pas plus de 60% en poids d'acide galacturonique, ledit procédé comprenant les étapes de:

- mise en suspension du matériel végétal de betterave dans un milieu aqueux pour former une suspension;
- ajustement du pH de ladite suspension à une valeur inférieure à 4,5 ou supérieure à 9,0;
- maintien de la suspension à une température supérieure à 125°C pendant une période de 15 à 600 secondes;
- cisaillement mécanique de ladite suspension; et
- isolement de ladite pectine de betterave à partir de ladite suspension.

2. Un procédé selon la revendication 1, dans lequel la pectine de betterave est partiellement hydrolysée et dissoute dans l'eau.

3. Un procédé pour conférer un produit comestible ou un médicament, autre que les produits à tartiner à base de fruits, les propriétés suivantes:

- (a) teneur réduite en calorie;
- (b) teneur en graisse réduite; ou
- (c) texture améliorée;
- (d) libération d'arôme amélioré; et
- (e) propriété gustative améliorée;

ledit produit comestible étant composé d'au moins un premier matériau dans au moins un second matériau, ledit procédé comprenant le mélange d'au moins de la pectine de betterave selon la revendication 1 ou 2 avec ledit produit comestible ou le médicament en une quantité suffisante pour conférer au moins l'une desdites propriétés audit produit comestible.

4. Le procédé selon la revendication 3, dans lequel le produit alimentaire est au moins un élément sélectionné dans le groupe consistant en: émulsions, mousses, pâte à crêpes et à beignets et pâtes à pétrir.

5. Le procédé selon la revendication 2, dans lequel le produit est un médicament.

Revendications pour l'Etat contractant suivant : GR

1. Pectine de betterave qui est retenue par une membrane d'ultra-filtration présentant un seuil de coupure correspondant à 30 000 Dalton et qui contient au moins 30% et pas plus de 60% en poids d'acide galacturonique, ladite pectine de betterave étant susceptible d'être préparée par:

- mise en suspension du matériel végétal de betterave dans un milieu aqueux pour former une suspension;
- ajustement du pH de ladite suspension à une valeur inférieure à 4,5 ou supérieure à 9,0;
- maintien de la suspension à une température supérieure à 125°C pendant une période de 15 à 600 secondes;
- cisaillement mécanique de ladite suspension; et
- isolement de ladite pectine de betterave à partir de ladite suspension.

2. Un produit comestible, autre que les produits à tartiner à base de fruits, présentant au moins l'une des propriétés suivantes:

- (a) teneur réduite en calorie;
- (b) teneur en graisse réduite;

- (c) texture améliorée;
- (d) libération d'arome amélioré; et
- (e) propriété gustative améliorée;

5 ledit produit comestible étant composé d'au moins un premier matériau dans au moins un second matériau, et comprenant au moins de la pectine de betterave selon la revendication 1 en une quantité suffisante pour conférer au moins l'une desdites propriétés audit produit comestible.

3. Le produit comestible selon la revendication 2, qui correspond à un produit alimentaire.

10 4. Le produit comestible selon la revendication 3, dans lequel ledit produit alimentaire est au moins un élément sélectionné dans le groupe consistant en: émulsions, mousses, pâte à crêpes et à beignets et pâtes à pétrir.

5. Un procédé pour conférer à un produit comestible ou à un médicament, autre que les produits à tartiner à base de fruits, les propriétés suivantes:

- (a) teneur réduite en calorie;
- (b) teneur en graisse réduite; ou
- (c) texture améliorée;
- (d) libération d'arome amélioré; et
- (e) propriété gustative améliorée;

20 ledit produit comestible comprenant au moins un premier matériau dans au moins un second matériau, ledit procédé comprenant le mélange d'au moins de la pectine de betterave selon la revendication 1 avec ledit produit comestible ou le médicament en une quantité suffisante pour conférer au moins l'une desdites propriétés audit produit comestible.

6. Pectine de betterave selon la revendication 1, qui est partiellement hydrolysée et dissoute dans l'eau.

30 7. Une composition comprenant une pectine de betterave partiellement hydrolysée selon la revendication 6 dissoute dans de l'eau.
